

class Calci

{

void add (int x, int y) {}

void add (float x, float y) {}

void add (int x, int y, int z) {}

}

Poly morphism:

1) showing different behaviour

2) has 2 types

- compile time poly → method overloading
- runtime poly → method overriding

method overloading

- one class consist of multiple method with same name

↳ 1) number of parameter must be diff.

2) if number of parameter are same then their datatype must be diff.

method overriding -

1. when child class wants to reimplement already implemented method in parent class then it is called as method overriding

→ why? - child is not satisfied with parent's implementation
- if parent has partially implemented method

2. even after reimplementation, child can access same method from parent using `super()`

getters and setters in encapsulation

- binding data members into single unit
- making all variables private

```
{ class Employee
  private String name;
  void setName(String ename) → write
  {
    this.name = ename;
  }
  String getName() → read
  {
    return this.name;
  }
}
```
